

TITLE OF THE INVENTION

Polymer, Resist Composition and Patterning Process

5 This invention relates to polymers suitable as the
base resin in chemically amplified positive resist
compositions used for micropatterning in a process for the
fabrication of semiconductor devices. It also relates to
chemically amplified positive resist compositions adapted
10 for exposure to high-energy radiation such as deep-UV, KrF
excimer laser light (248 nm), ArF excimer laser light (193
nm), electron beams or x-rays and a process for forming a
pattern.

BACKGROUND OF THE INVENTION

15 While a number of recent efforts are being made to
achieve a finer pattern rule in the drive for higher
integration and operating speeds in LSI devices, the
commonly used light exposure technology is approaching the
20 essential limit of resolution determined by the light source
wavelength. For the light exposure using g-line (436 nm) or
i-line (365 nm), a pattern rule of about 0.5 μ m is thought
to be the limit. The LSI fabricated using such light
25 exposure has a maximum degree of integration corresponding
to 16 M-bit dynamic random access memory (DRAM). However,
the laboratory fabrication of LSI already reached this stage,
and the development of a further micropatterning technology
is in urgent demand.

30 One means for reducing the pattern size is to reduce
the wavelength of exposure light used in forming a resist
pattern. For the mass production process of 256 M-bit DRAM
(processing size up to 0.25 μ m), it is now under intensive
consideration to replace i-line (365 nm) as the exposure
35 light source by KrF excimer laser light of a shorter
wavelength of 248 nm. However, for the fabrication of DRAM
with a degree of integration of 1 G or more requiring a

finer patterning technology (processing size up to 0.2 μm), a shorter wavelength light source is required, and in particular, photolithography using ArF excimer laser light (193 nm) is now under investigation.

5 Since H. Ito, G. C. Willson et al of IBM proposed a chemically amplified positive resist composition comprising a resin in the form of polyhydroxystyrene having hydroxyl groups blocked with tert-butoxycarbonyloxy (tBOC) groups, that is, poly(4-t-butoxycarbonyloxystyrene) (PBOCST) and a
10 photoacid generator in the form of an onium salt, a number of resist compositions having a high sensitivity and resolution have been developed. These chemically amplified positive resist compositions all have a high sensitivity and resolution, but are difficult to form fine patterns with a
15 high aspect ratio because the patterns' mechanical strength is low.

 A number of chemically amplified positive resist compositions using the above-mentioned polyhydroxystyrene as the base resin and having sensitivity to deep-UV, electron
20 beams and x-rays are known in the art. These resist compositions, however, rely on the single-layer resist method although the bi-layer resist method is advantageous in forming a pattern with a high aspect ratio on a stepped substrate. These resist compositions are not yet
25 practically acceptable because of the outstanding problems of substrate steps, light reflection from substrates, and difficulty of forming high-aspect ratio patterns.

 As is known in the art, the bi-layer resist method is advantageous in forming a high-aspect ratio pattern on a
30 stepped substrate. It is also known that in order to develop a bi-layer resist film with a common alkaline developer, high molecular weight silicone compounds having hydrophilic groups such as hydroxyl and carboxyl groups must be used.

35 Among silicone base chemically amplified positive resist compositions, recently proposed were those compositions comprising a base resin in the form of

polyhydroxybenzylsilsesquioxane, which is a stable alkali-soluble silicone polymer, in which some phenolic hydroxyl groups are blocked with tBOC groups, in combination with a photoacid generator (see JP-A 7-118651 and SPIE vol. 1925 (1993), 377). Also JP-A 9-110938 discloses a silicone-containing polymer using a silicon-containing acrylic monomer.

The silicon-containing polymer of the acrylic pendant type has the drawback that its resistance to dry etching with oxygen plasma is weak as compared with The silsesquioxane polymer. A low silicon content accounts for this weak dry etching resistance. The silicon-containing polymer of the siloxane pendant type has the drawback that it is repellent to developer and less wettable therewith. Then SPIE vol. 3678, pp. 214, 241 and 562 describes a polymer containing a monomer of the trisilane or tetrasilane pendant type having an increased silicon content and a silicon-containing substituent which can be eliminated with acid. However, since silane compounds of at least disilane exhibit strong absorption at the wavelength of ArF excimer laser, an increased introduction of such silanes undesirably leads to a lower transmittance. Besides, an attempt of introducing silicon into acid labile groups is reported in SPIE vol. 3678, p. 420. Because of a low acid elimination ability, there are drawbacks including low environmental stability and a T-top profile.

SUMMARY OF THE INVENTION

An object of the invention is to provide a novel polymer which is useful as the base polymer in a chemically amplified positive resist composition having a high sensitivity and high resolution, especially suitable as a material for use in the bi-layer resist method adapted to form a high-aspect ratio pattern, and capable of forming a pattern having improved heat resistance. Another object of the invention is to provide a chemically amplified positive

The polymer is prepared in a conventional manner by furnishing predetermined amounts of a monomer having a silicon-containing group of formula (1), preferably a monomer or monomers capable of forming units of the formulae (2) through (5) and optionally, a monomer or monomers capable of forming units of formulae (2A) to (5A), a monomer or monomers capable of forming units of formulae (53) to (90) and a monomer or monomers capable of forming units of formulae (Si-1) to (Si-5), mixing the monomers in a solvent,

adding a catalyst, and effecting polymerization reaction while heating or cooling if necessary. The polymerization reaction depends on the type of initiator (or catalyst), trigger means (light, heat, radiation or plasma), and polymerization conditions (including temperature, pressure, concentration, solvent and additive). Commonly used for the preparation of the inventive polymer are a radical copolymerization mode utilizing a radical of 2,2'-azobisisobutyronitrile (AIBN) etc. for initiating polymerization and an ionic polymerization (anionic polymerization) mode using alkyl lithium catalysts. In either mode, polymerization can be done in a conventional manner. It is understood that the monomers capable of forming units of formulae (2) to (5) can be synthesized by the procedure described in Synthesis Example 1 or analogous procedures.

The polymer of the invention can be represented by the following formula.

tris(p-tert-butoxyphenyl)sulfonium p-toluenesulfonate;
diazomethane derivatives such as bis(benzenesulfonyl)diazomethane, bis(p-toluenesulfonyl)diazomethane, bis(cyclohexylsulfonyl)diazomethane, bis(n-butylsulfonyl)diazomethane,
5 bis(isobutylsulfonyl)diazomethane, bis(sec-butylsulfonyl)diazomethane, bis(n-propylsulfonyl)diazomethane, bis(isopropylsulfonyl)diazomethane, and bis(tert-butylsulfonyl)diazomethane; and glyoxime derivatives such as bis-O-(p-toluenesulfonyl)- α -dimethylglyoxime and bis-O-(n-
10 butanesulfonyl)- α -dimethylglyoxime. These photoacid generators may be used singly or in combinations of two or more thereof. Onium salts are effective for improving rectangularity, while diazomethane derivatives and glyoxime derivatives are effective for reducing standing waves. The
15 combination of an onium salt with a diazomethane or a glyoxime derivative allows for fine adjustment of the profile.

The photoacid generator is added in an amount of 0.2 to 15 parts by weight, and especially 0.5 to 8 parts by weight, per 100 parts by weight of all the base resins. At
20 less than 0.2 part, the amount of acid generated during exposure would be too low and the sensitivity and resolution are poor, whereas the addition of more than 15 parts would lower the transmittance of the resist and results in a poor
25 resolution.

Dissolution rate inhibitor (D)

To the resist composition, a dissolution rate inhibitor may be added. The dissolution rate inhibitor is a compound having on the molecule at least two phenolic
30 hydroxyl groups, in which an average of from 0 to 100 mol% of all the hydrogen atoms on the phenolic hydroxyl groups are replaced with acid labile groups or a compound having on the molecule at least one carboxyl group, in which an average of 10 to 100 mol% of all the hydrogen atoms on the
35 carboxyl groups are replaced with silicon-containing groups of formula (1), both the compounds having an average

molecular weight within a range of 100 to 1,000, and preferably 150 to 800.

The degree of substitution of the hydrogen atoms on the phenolic hydroxyl groups with acid labile groups is on average at least 0 mol%, and preferably at least 30 mol%, of all the phenolic hydroxyl groups. The upper limit is 100 mol%, and preferably 80 mol%. The degree of substitution of the hydrogen atoms on the carboxyl groups with acid labile groups is on average at least 50 mol%, and preferably at least 70 mol%, of all the carboxyl groups, with the upper limit being 100 mol%.

Preferable examples of such compounds having two or more phenolic hydroxyl groups or compounds having at least one carboxyl group include those of formulas (D1) to (D14) below.

5 formulated in an amount of 0.01 to 2 parts by weight, and

effects of the basic compound would not be apparent, while
the use of more than 2 parts would result in too low a
10 sensitivity.

The resist composition of the invention may include
optional ingredients, typically a surfactant which is
commonly used for improving the coating characteristics.

15 long as this does not compromise the objects of the
invention.

30 Pattern formation using the resist composition of the
invention may be carried out by a known lithographic
technique. For example, the resist composition is applied
onto an organic film on a substrate such as a novolac film
of about 0.1 to 10.0 μm thick on a silicon wafer by spin
35 coating or the like to form a resist film having a thickness
of 0.1 to 1.0 μm , which is then pre-baked on a hot plate at
60 to 200°C for 10 seconds to 10 minutes, and preferably at

80 to 150°C for 30 seconds to 5 minutes. A patterning mask having the desired pattern is then placed over the resist film, and the film is exposed through the mask to an electron beam or high-energy radiation having a wavelength of up to 300 nm such as deep-UV, an excimer laser, or x-rays in a dose of about 1 to 200 mJ/cm², and preferably about 10 to 100 mJ/cm², then post-exposure baked (PEB) on a hot plate at 60 to 150°C for 10 seconds to 5 minutes, and preferably at 80 to 130°C for 30 seconds to 3 minutes. Development is then carried out using as the developer an aqueous alkali solution, such as a 0.1 to 5% (preferably 2 to 3%) aqueous solution of tetramethylammonium hydroxide (TMAH), this being done by a conventional method such as dipping, puddling, or spraying for a period of 10 seconds to 3 minutes, and preferably 30 seconds to 2 minutes. These steps result in the formation of the desired pattern on the substrate. Of the various types of high-energy radiation that may be used, the resist composition of the invention is best suited to micropattern formation with, in particular, deep-UV rays and excimer laser light having a wavelength of 254 to 120 nm, especially KrF excimer laser of 248 nm or ArF excimer laser of 193 nm, x-rays, and an electron beam. The desired pattern may not be obtainable outside the upper and lower limits of the above range.

In the developing step, the exposed area of the resist film is dissolved away until the underlying organic film is exposed. Then the exposed area of the organic film is conventionally processed with an oxygen plasma generated by a dry etching apparatus.

The resist composition comprising the polymer of the invention as a base resin is sensitive to high-energy radiation and has excellent sensitivity and resolution at a wavelength of less than 300 nm, and high resistance to oxygen plasma etching. Because of these advantages, the resist composition is suited for bi-layer resist and easily forms a finely defined pattern having sidewalls

perpendicular to the substrate. The resist composition lends itself to micropatterning for the fabrication of VLSIs.

Synthesis Example 2-1: Synthesis of Polymer 1

In 100 ml of THF were dissolved 12.0 g of Monomer 1 and 6.8 g of 2-oxo-2,3,4,5-tetrahydrofuran-3-yl methacrylate. Then 1.6 g of 2,2'-azobisisobutyronitrile was added thereto. The resulting solids were collected by filtration, washed with 1 liter of n-hexane, and vacuum dried at 40°C for 6 hours, obtaining 11.8 g of a polymer shown below as Polymer 1. The yield was 63%. Resist compositions within the scope of the invention were examined for resolution upon KrF excimer laser exposure.

5 Examples 1-28: Resist resolution

5 On silicon wafers, lower resist films of 0.5 μm thick were formed by applying novolac resist material OFPR-800 (Tokyo Ohka Kogyo Co., Ltd.) and heating at 300°C for 5 minutes for curing. Antireflection films of 55 nm thick were formed thereon by spin coating DUV-30 (Brewer Science) and baking at 100°C for 30 seconds and then at 200°C for 60 seconds.

15 On the cured DUV-30/novolac resist/silicon wafer, the resist solutions were spin coated, then baked on a hot plate at 100°C for 90 seconds to give resist films of 0.2 μm thick. Using a KrF excimer laser stepper (Nikon Corporation, NA 0.60), the resist films were exposed. The resist films were baked (PEB) at 110°C for 90 seconds and then developed with a 2.38% aqueous solution of tetramethylammonium hydroxide, obtaining positive patterns.

20 The sensitivity of the resist was the exposure dose (mJ/cm^2) which provided a 1:1 line-to-space ratio in a 0.20 μm line-and-space pattern. The resolution of the resist was the minimum line width (μm) of the lines and spaces that separated at this dose.

25 Using a parallel plate sputter etching apparatus TE-8500 by Tokyo Electron Co., Ltd., the resist films were etched with an etchant, oxygen gas under the following conditions.

30 Oxygen gas flow rate: 0.05 l/min

Gas pressure: 1.3 Pa

RF power: 50 W

DC bias: 450 V

35 The lower resist film was etched at a rate of 150 nm/min whereas the inventive resist film was etched at a rate of 15 nm/min. After 2 minutes of etching, those portions of the lower resist film which were not covered

with the inventive resist film disappeared completely,
leaving a bi-layer resist pattern having a thickness of 0.5
 μm .

The evaluation results of the resists are shown in

5 Table 1.
